Data Cleaning

Data Wrangling in R

Data Cleaning

In general, data cleaning is a process of investigating your data for inaccuracies, or recoding it in a way that makes it more manageable.

MOST IMPORTANT RULE - LOOK AT YOUR DATA!

Useful checking functions

- is.na is TRUE if the data is FALSE otherwise
- · ! negation (NOT)
 - if is.na(x) is TRUE, then !is.na(x) is FALSE
- all takes in a logical and will be TRUE if ALL are TRUE
 - all(!is.na(x)) are all values of x NOT NA
- any will be TRUE if ANY are true
 - any(is.na(x)) do we have any NA's in x?
- complete.cases returns TRUE if EVERY value of a row is NOT NA
 - very stringent condition
 - FALSE missing one value (even if not important)

Dealing with Missing Data

Missing data types

One of the most important aspects of data cleaning is missing values.

Types of "missing" data:

- NA general missing data
- NaN stands for "Not a Number", happens when you do 0/0.
- Inf and -Inf Infinity, happens when you take a positive number (or negative number) by 0.

Finding Missing data

Each missing data type has a function that returns **TRUE** if the data is missing:

- NA is.na
- NaN is.nan
- Inf and -Inf is.infinite
- is.finite returns FALSE for all missing data and TRUE for non-missing

Missing Data with Logicals

One important aspect (esp with subsetting) is that logical operations return NA for NA values. Think about it, the data could be > 2 or not we don't know, so R says there is no TRUE or FALSE, so that is missing:

$$x = c(0, NA, 2, 3, 4)$$

 $x > 2$
[1] FALSE NA FALSE TRUE TRUE

Missing Data with Logicals

What to do? What if we want if x > 2 and x isn't NA? Don't do x != NA, do x > 2 and x is NOT NA:

```
x != NA
[1] NA NA NA NA NA
x > 2 & !is.na(x)
[1] FALSE FALSE FALSE TRUE TRUE
```

Missing Data with Logicals

What about seeing if a value is equal to multiple values? You can do $(x = 1 \mid x = 2) \& !is.na(x)$, but that is not efficient.

$$(x == 0 \mid x == 2) \# has NA$$

[1] TRUE NA TRUE FALSE FALSE

 $(x == 0 \mid x == 2) \& !is.na(x) \# No NA$

[1] TRUE FALSE TRUE FALSE FALSE what to do?

Missing Data with Logicals: %in%

Introduce the **%in%** operator:

```
x %in% c(0, 2) # NEVER has NA and returns Logical
[1] TRUE FALSE TRUE FALSE FALSE
reads "return TRUE if x is in 0 or 2". (Like inlist in Stata).
```

Missing Data with Logicals: %in%

NEVER has NA, even if you put it there (BUT DON'T DO THIS):

```
x %in% c(0, 2, NA) # NEVER has NA and returns Logical
[1] TRUE TRUE TRUE FALSE FALSE
x %in% c(0, 2) | is.na(x)
[1] TRUE TRUE TRUE FALSE FALSE
```

Missing Data with Operations

Similarly with logicals, operations/arithmetic with NA will result in NAs:

```
x + 2
[1] 2 NA 4 5 6
x * 2
[1] 0 NA 4 6 8
```

Tables and Tabulations

Useful checking functions

- unique gives you the unique values of a variable
- table(x) will give a one-way table of x
 - table(x, useNA = "ifany") will have row NA
- table(x, y) will give a cross-tab of x and y

Creating One-way Tables

Here we will use table to make tabulations of the data. Look at ?table to see options for missing data.

Creating One-way Tables

useNA = "ifany" will not have NA in table heading if no NA:

Creating One-way Tables

You can set useNA = "always" to have it always have a column for NA

Tables with Factors

If you use a factor, all levels will be given even if no exist! - (May be wanted or not):

Creating Two-way Tables

A two-way table. If you pass in 2 vectors, table creates a 2-dimensional table.

```
tab <- table(c(0, 1, 2, 3, 2, 3, 3, 2,2, 3),

c(0, 1, 2, 3, 2, 3, 3, 4, 4, 3),

useNA = "always")
```

Recoding to missing

Sometimes people code missing data in weird or inconsistent ways.

```
ages = c(23,21,44,32,57,65,-999,54) range(ages)
[1] -999 65
```

Recoding to missing

How do we change the -999 to be treated as missing?

```
ages[ages == -999] = NA
range(ages)

[1] NA NA
range(ages,na.rm=TRUE)

[1] 21 65
```

Recoding from missing

```
What if you were the person that coded the -999
is.na(ages)
[1] FALSE FALSE FALSE FALSE FALSE TRUE FALSE
ages[is.na(ages)] = -999
ages
[1] 23 21 44 32 57 65 -999 54
```

Read in the UFO dataset

 Read in data from RStudio Cloud or download from: http://sisbid.github.io/Module1/data/ufo/ufo_data_complete.csv.gz

```
ufo = read csv("../data/ufo/ufo data complete.csv")
Parsed with column specification:
cols(
  datetime = col character(),
  city = col_character(),
  state = col_{character}(),
  country = col_character(),
  shape = col_character(),
  `duration (seconds)` = col_double(),
  \hat{a} duration (hours/min) = \hat{col} character(),
  comments = col_character(),
  `date posted` = col character(),
  latitude = col_character(),
  longitude = col_double()
Warning in rbind(names(probs), probs f): number of columns of result is not
a multiple of vector length (arg 1)
                                                                       23/57
```

Checking for logical conditions

```
    any() - checks if there are any TRUEs
    all() - checks if ALL are true
    any(is.na(ufo$state)) # are there any NAs?
    [1] TRUE
    table(is.na(ufo$state)) # are there any NAs?
    FALSE TRUE
    81356 7519
```

Recoding Variables

Example of Recoding: base R

For example, let's say gender was coded as Male, M, m, Female, F, f. Using Excel to find all of these would be a matter of filtering and changing all by hand or using if statements.

In R, you can simply do something like:

Example of Cleaning: more complicated

Sometimes though, it's not so simple. That's where functions that find patterns come in very useful.

```
table(gender)
gender
     F FeMAle FEMALE
                                             mAle
                                                    Male
                         Fm
                                 Μ
                                                           MaLe
                                                                  MALE
                                        Ma
    75
                         89
                                89
                                        79
                                               87
                                                      89
                                                             88
           82
                  74
                                                                     95
   Man Woman
           80
    73
```

String functions

Useful String Functions

Useful String functions

- toupper(), tolower() uppercase or lowercase your data:
- str_trim() (in the stringr package) or trimws in base
 - will trim whitespace
- nchar get the number of characters in a string
- paste() paste strings together with a space
- paste0 paste strings together with no space as default

Pasting strings with paste and paste0

Paste can be very useful for joining vectors together:

```
paste("Visit", 1:5, sep = "_")
[1] "Visit_1" "Visit_2" "Visit_3" "Visit_4" "Visit_5"
paste("Visit", 1:5, sep = "_", collapse = " ")
[1] "Visit 1 Visit 2 Visit 3 Visit 4 Visit 5"
paste("To", "is going be the ", "we go to the store!", sep = "day ")
[1] "Today is going be the day we go to the store!"
# and paste0 can be even simpler see ?paste0
paste0("Visit",1:5)
[1] "Visit1" "Visit2" "Visit3" "Visit4" "Visit5"
```

Paste Depicting How Collapse Works

```
paste(1:5)
[1] "1" "2" "3" "4" "5"

paste(1:5, collapse = " ")
[1] "1 2 3 4 5"
```

The stringr package

Like dplyr, the stringr package:

- Makes some things more intuitive
- · Is different than base R
- Is used on forums for answers
- Has a standard format for most functions
 - the first argument is a string like first argument is a data.frame in dplyr

Splitting/Find/Replace and Regular Expressions

- · R can do much more than find exact matches for a whole string
- Like Perl and other languages, it can use regular expressions.
- What are regular expressions?
 - Ways to search for specific strings
 - Can be very complicated or simple
 - Highly Useful think "Find" on steroids

A bit on Regular Expressions

- http://www.regular-expressions.info/reference.html
- They can use to match a large number of strings in one statement
- · . matches any single character
- * means repeat as many (even if 0) more times the last character
- · ? makes the last thing optional
- ^ matches start of vector ^a starts with "a"
- \$ matches end of vector b\$ ends with "b"

Splitting Strings

Substringing

Very similar:

Base R

- substr(x, start, stop) substrings from position start to position stop
- strsplit(x, split) splits strings up returns list!

stringr

- str_sub(x, start, end) substrings from position start to position end
- str_split(string, pattern) splits strings up returns list!

Splitting String: base R

In base R, strsplit splits a vector on a string into a list

Splitting String: stringr

Using a fixed expression

One example case is when you want to split on a period ".". In regular expressions . means **ANY** character, so

```
str_split("I.like.strings", ".")

[[1]]
[1] "" "" "" "" "" "" "" "" "" "" "" ""

str_split("I.like.strings", fixed("."))

[[1]]
[1] "I" "like" "strings"
```

Let's extract from y

```
suppressPackageStartupMessages(library(dplyr)) # must be Loaded AFTER plyr
y[[2]]
[1] "like" "writing"
sapply(y, dplyr::first) # on the fly
[1] "I" "like" "R"
sapply(y, nth, 2) # on the fly
[1] "really" "writing" "code"
sapply(y, last) # on the fly
[1] "really" "writing" "programs"
```

'Find' functions: base R

grep: grep, grep1, regexpr and gregexpr search for matches to argument pattern within each element of a character vector: they differ in the format of and amount of detail in the results.

grep(pattern, x, fixed=FALSE), where:

- pattern = character string containing a regular expression to be matched in the given character vector.
- x = a character vector where matches are sought, or an object which can be coerced by as.character to a character vector.
- If fixed=TRUE, it will do exact matching for the phrase anywhere in the vector (regular find)

'Find' functions: stringr

str_detect, str_subset, str_replace, and str_replace_all search for matches to argument pattern within each element of a character vector: they differ in the format of and amount of detail in the results.

- str_detect returns TRUE if pattern is found
- str_subset returns only the strings which pattern were detected
 - convenient wrapper around x[str_detect(x, pattern)]
- str_extract returns only strings which pattern were detected, but ONLY the pattern
- str_replace replaces pattern with replacement the first time
- str_replace_all replaces pattern with replacement as many times matched

'Find' functions: stringr compared to base R

Base R does not use these functions. Here is a "translator" of the stringr function to base R functions

- str_detect similar to grep1 (return logical)
- grep(value = FALSE) is similar to which(str_detect())
- str_subset similar to grep(value = TRUE) return value of matched
- str_replace similar to sub replace one time
- str_replace_all similar to gsub replace many times

Let's look at modifier for stringr

?modifiers

- fixed match everything exactly
- regexp default uses regular expressions
- ignore_case is an option to not have to use tolower

Important Comparisons

Base R:

- Argument order is (pattern, x)
- Uses option (fixed = TRUE)

stringr

- Argument order is (string, pattern) aka (x, pattern)
- Uses function fixed(pattern)

'Find' functions: Finding Indices

These are the indices where the pattern match occurs:

```
grep("two aliens",ufo$comments)
[1] 1730 61724
which(grep1("two aliens", ufo$comments))
[1] 1730 61724
which(str_detect(ufo$comments, "two aliens"))
[1] 1730 61724
```

'Find' functions: Finding Logicals

These are the indices where the pattern match occurs:

```
grepl("two aliens", ufo$comments)
```

```
FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE
         FALSE FALSE FALSE FALSE FALSE FALSE
    FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE
                   FALSE FALSE FALSE
                   FALSE FALSE FALSE
         FALSE FALSE FALSE FALSE FALSE
                   FALSE FALSE FALSE FALSE
    FALSE FALSE FALSE FALSE FALSE
                   FALSE FALSE FALSE
         FALSE FALSE FALSE FALSE FALSE
FALSE FALSE FALSE FALSE FALSE FALSE FALSE
                   FALSE FALSE FALSE FALSE
         FALSE FALSE FALSE FALSE FALSE
                   FALSE FALSE FALSE
                   FALSE FALSE FALSE
                   FALSE FALSE FALSE FALSE
         FALSE FALSE
                   FALSE FALSE FALSE FALSE FALSE FALSE
    FALSE FALSE FALSE
    FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE
FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE FALSE
```

'Find' functions: finding values, base R

latitude <chr>, longitude <dbl>

```
grep("two aliens", ufo$comments, value=TRUE)
[1] "((HOAX??)) two aliens appeared from a bright light to peacefully investigate the surroundings in the woods
[2] "Witnessed two aliens walking along baseball field fence."
ufo[grep("two aliens",ufo$comments),]
# A tibble: 2 x 11
 datetime city state country shape `duration (seco~ `duration (hour~
           <chr> <chr> <chr> <chr>
                                                <dbl> <chr>
 <chr>
1 10/14/20~ yuma
                                                  300 5 minutes
                        us
                                forma~
                   va
2 7/1/2007~ north ~ ct
                              unkno~
                                                   60 1 minute
                        <NA>
# ... with 4 more variables: comments <chr>, `date posted` <chr>,
```

'Find' functions: finding values, stringr and dplyr

latitude <chr>, longitude <dbl>

```
str subset(ufo$comments, "two aliens")
[1] "((HOAX??)) two aliens appeared from a bright light to peacefully investigate the surroundings in the woods
[2] "Witnessed two aliens walking along baseball field fence."
ufo %>% filter(str detect(comments, "two aliens"))
# A tibble: 2 x 11
 datetime city state country shape `duration (seco~ `duration (hour~
 <chr>
           <chr> <chr> <chr> <chr>
                                               <dbl> <chr>
1 10/14/20~ yuma
                                forma~
                                                  300 5 minutes
                   va
                         us
2 7/1/2007~ north ~ ct
                         <NA>
                                unkno~
                                                   60 1 minute
# ... with 4 more variables: comments <chr>, `date posted` <chr>,
```

Showing differnce in str_extract

```
str_extract extracts just the matched string
ss = str_extract(ufo$comments, "two aliens")
head(ss)

[1] NA NA NA NA NA NA
ss[ !is.na(ss)]

[1] "two aliens" "two aliens"
```

Using Regular Expressions

Look for anycomment that starts with "aliens"

```
grep("^aliens.*", x = ufo$comments, value = TRUE)

[1] "aliens speak german???" "aliens exist"
[3] "aliens in srilanka"

head(grep("space.?ship", x = ufo$comments, value = TRUE),3)

[1] "I saw the cylinder shaped looked like a spaceship hovring above the eas [2] "description of a spaceship spotted over Birmingham Alabama in 1967."
[3] "A space ship was descending to the ground"
```

Using Regular Expressions: stringr

```
grep("^aliens.*", x = ufo$comments, value = TRUE)

[1] "aliens speak german???" "aliens exist"
[3] "aliens in srilanka"

head(str_subset( ufo$comments, "space.?ship"),3)

[1] "I saw the cylinder shaped looked like a spaceship hovring above the eas [2] "description of a spaceship spotted over Birmingham Alabama in 1967."
[3] "A space ship was descending to the ground"
```

Replace

Let's say we wanted to sort the data set by latitude and longitude:

class(ufo\$latitude)

[1] "character"

sort(c("1", "2", "10")) # not sort correctly (order simply ranks the data)

[1] "1" "10" "2"

order(c("1", "2", "10"))

[1] 1 3 2

Replace

So we must change the coordinates into a numeric:

```
head(ufo$latitude, 4)

[1] "29.8830556" "29.38421" "53.2" "28.9783333"

head(as.numeric(ufo$latitude), 4)

Warning in head(as.numeric(ufo$latitude), 4): NAs introduced by coercion

[1] 29.88306 29.38421 53.20000 28.97833
```

Dropping bad observations

Ordering

Replacing and subbing: stringr

We can do the same thing (with 2 piping operations!) in dplyr

```
ufo_dplyr = ufo_clean
ufo dplyr = ufo dplyr %>% mutate(
 latitude = latitude %>% as.numeric,
 longitude = longitude %>% as.numeric) %>%
   arrange(latitude,longitude)
ufo_dplyr[1:5, c("datetime", "latitude", "longitude")]
# A tibble: 5 x 3
 datetime
                  latitude longitude
 <chr>>
                     <dbl>
                              <dbl>
1 5/15/1994 13:00 -82.9
                           -135
2 4/14/2002 22:22 -46.4
                           168.
3 7/3/2002 22:35 -46.4
                              168.
                               170.
4 10/23/2008 04:45
                   -46.2
5 6/1/1998 22:00
                     -45.7
                               171.
```
